# The morphology of the regular $\&$ semi-regular polyhedra and tessellations according to the separation of facial polytopes 

Robert C. Meurant<br>Director Emeritus, Institute of Traditional Studies; Adjunct Professor, Seoul National University PG College of Eng.; Exec. Director, Research \& Education, Harrisco Enco 4/1108 Shin-Seung Apt, ShinGok-Dong 685 Bungi, Uijeongbu-Si, Gyeonggi-Do 11741, Republic of Korea. rmeurant@gmail.com• http://www.rmeurant.com/its/

#### Abstract

In previous work, inspired by Critchlow [1], and by Grünbaum \& Shephard [2], I proposed an integral 2.5 D cubic schema of the regular and semi-regular polyhedra and polygonal tessellations of the plane for each class of symmetry, which could be differentiated into an upper and lower layer of 4 polytopes each, and characterized by corresponding pairs, so that upper polytope always corresponds to lower [3]. I explored the motif of paired two-step sequences of first alternating facial separation and morphological transformation, and second facial morphological transformation and separation, which in the 2D consideration of the 2.5 D schema are disposed about the vertical axis, as characterized by the correspondence between the PPs of the lower and upper squares (diamonds or rhombi).

Following sustained research [3-11], I here focus on a deeper pattern of morphological transformation of the primary prototypes that is characterized by the separation of one gendered set of the negative (-ve), neutral (ntrl), or positive ( +ve ) facial polytopes along the Y, Z, \& X axes of the cubic schema. As one set of faces separates, the other two sets morph/ project if polar/neutral, through null $\rightarrow$ regular or quasi-regular $\rightarrow$ double facial levels $(0 \rightarrow \alpha \mid \beta \rightarrow 2)$ of the rhombic schema or its reflection. Each facial set separates just once: $\mathrm{d}=0 \rightarrow 1$. The cubic schema reveals significant three-fold symmetry by gender. The separation of faces provides an adequate schema for the morphology of the three classes of the regular and semi-regular polyhedra of $\{2,3,3\},\{2,3,4\}$, and $\{2,3,5\}$ symmetry, and two classes of polygonal tessellations (tilings) of $\{2,3,6\}$ and $\{2,4,4\}$ symmetry. (Kindly refer to Nomenclature at the end of paper).

Key words: polyhedra, tessellations, morphology, separation of faces

## 1. PAIRING OF POLYHEDRA BY THE SEPARATION OF FACES: CLASS II \& GENERIC

The pairings of polyhedra within any one class can be characterized by the separation of one set of the negative, neutral, or positive surface polytopes on the $\mathrm{Y}, \mathrm{Z}$, or X axes, respectively, of the 2.5 D schema, as in Fig. 1. Therefore, three significant kinds of pairings of $P P \mathrm{~s}$ can be made in the 2.5 D schema, dependent on the schema orthogonal axis. For descriptive convenience, this is described for Class II of $\{2,3,4\}$ symmetry, where the -ve , neutral, and + ve axes of the class, and thus of each of its individual polytopes, are conveniently the $\sqrt{ } 1, \sqrt{ } 2$, and $\sqrt{ } 3(100,110,111)$ axes of the cube, respectively.

This class is of 3D polyhedra, and the +ve and -ve polar polytopes take different forms (unlike Class I of 3D polyhedra, where the polar polytopes take the same form of the tetrahedron, though in alternative orientation, or Class V of 2D polygons, where both polar polytopes also take the same form of the square, but in different location). In the other classes, the symmetry axes are not in general orthogonal; in addition, Class II (leaving aside the transitional Snub form) precisely constitutes the PPs of the Class III honeycombs, so are the primary components of the Class III honeycomb periodic all-space-filling arrays. Subsequently, I compare this Class II with Class IV, to illustrate the differences between 3D polyhedral and 2D polygonal form, while considering classes with different polar polytopes, as opposed to having the same, but reoriented (3D) or relocated (2D) form. Contemplation of Fig. 1 reveals the beautiful integrity of interrelationship:

Fig. 1: Pairings of the Class II polyhedra according to -ve (left), ntrl (upper), or +ve (right) faces, which separate from adjoining (sharing a $V$ or $E$ ) to adjacent by distance unit $1=$ edge length. $C B$ and $O H$ are considered the -ve and +ve polar polytopes, respectively, with facial $P T \mathrm{~s}$ shown as -ve (cyan) \& +ve (magenta), respectively, with ntrl polytopes are shown in yellow, or thick black edge.

Table I. Separating PP pairs for Class II and their source and goal polytopes.

| Negative |  |  | Neutral |  |  | Positive |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Separating <br> facial $P T \mathrm{~s}$ | Source <br> polytope | Goal <br> polytope | Separating <br> facial $P T \mathrm{~s}$ | Source <br> polytope | Goal <br> polytope | Separating <br> facial $P T \mathrm{~s}$ | Source <br> polytope | Goal <br> polytope |
| $V^{-}$ | $V P_{2}$ | $O H$ | $V^{0}$ | $V P_{2}$ | $C O$ | $V^{+}$ | $V P_{2}$ | $C B$ |
| $S Q^{-}$ | $C B$ | $S R C O$ | $E_{\alpha}^{0}$ | $O H$ | $T O$ | $T R^{+}$ | $O H$ | $S R C O$ |
| $R S^{-}$ | $C O$ | $T O$ | $E_{\beta}^{0}$ | $C B$ | $T C$ | $R T^{+}$ | $C O$ | $T C$ |
| $O G^{-}$ | $T C$ | $G R C O$ | $S Q^{0}$ | $S R C O$ | $G R C O$ | $H X^{+}$ | $T O$ | $G R C O$ |

$N B$. In this paper, I modify my previous conventions, so Vertex $V T \rightarrow V$; neutral vertex $N V \rightarrow V^{0}$; edge $E G \rightarrow E$, neutral edge $N E \rightarrow E^{0}$; neutral square $N S \rightarrow S Q^{0}$; Facial polytope $\rightarrow F$; on-axis $0 \mathrm{D} V^{0}$ (the 1-gon, of $1 E \& 1 V^{0}$ ) \& 1D $E^{0}$ (the 2-gon, of $2 E \& 2 V^{0}$ ), \& 2D polygons ( $T R, H X, S Q, \ldots$ ), are considered $F$; see Nomenclature at end.

On the Y-axis of the schema (going leftwards), negative faces separate (cyan; lower left). Adjoining (coincident) $V^{-}$s of the $V P$ separate to adjacent $V^{-}$s of the $O H$ (its nodes); adjoining $S Q^{-} \mathrm{s}$ of the $C B$ separate to adjacent $S Q^{-}$s of the $S R C O$; adjoining $R S^{-}$s of the $C O$ separate to adjacent $R S^{-}$s of the $T O$; and adjoining $O G^{-}$s of the $T C$ separate to adjacent $O G^{-}$s of the GRCO. In each case, adjoining pairs of negative polytopes of a $P P$ that share a $V^{0}$ or $E^{0}$ separate by edge length unit distance 1 to adjacent negative polytopes of its $P P$ pair.

On the Z-axis of the schema (going upwards), neutral faces separate (yellow; upper). Adjoining (coincident) $V^{0}$ s of the $V P$ separate to adjacent $V^{0}$ s of the $C O$ (its nodes); adjoining $E^{0} \mathrm{~s}$ of the $O H$ separate to adjacent $E^{0} \mathrm{~S}$ of the $T O$; adjoining $E^{0} \mathrm{~s}$ of the $C B$ separate to adjacent $E^{0} \mathrm{~S}$ of the $T C$; and adjoining $S Q^{0}$ s of the $S R C O$ separate to adjacent $S Q^{0}$ s of the GRCO. In each case, adjoining pairs of neutral surface polytopes of a $P P$, sharing a $V$ or $E$ that need not be $+/ 0 /-$ ve, e.g., of $S R C O$, separate by $\mathrm{d}=1$ to adjacent neutral $F \mathrm{~s}$ of its $P P$ pair.

On the X -axis of the schema (going rightwards), positive faces separate (magenta; lower right). Adjoining (coincident) $V^{+} \mathrm{s}$ of the $V P$ separate to adjacent $V^{+} \mathrm{s}$ of the $C B$ (its nodes); adjoining $T R^{+} \mathrm{s}$ of the $O H$ separate to adjacent $T R^{+} \mathrm{s}$ of the $S R C O$; adjoining $R T^{+} \mathrm{s}$ of the $C O$ separate to adjacent $R T^{+} \mathrm{s}$ of the $T C$; \& adjoining $H X^{+}$s of the $T O$ separate to adjacent $\mathrm{HX}^{+}$s of the GRCO. In each case, adjoining pairs of positive polytopes of a $P P$ sharing $V^{0}$ or $E^{0}$ separate by $\mathrm{d}=1$ to adjacent +ve polytopes of its $P P$ pair.

These various correspondences by separation of facial polytopes by unit distance can be combined into the one illustration (Fig. 2), shown at left \& middle for Class II, and at right for all classes. Again, in each case of facial separation, adjoining pairs of polytopes of a $P P(\mathrm{~d}=0)$ separate by unit distance $\mathrm{d}=1(=$ length of polytope side) to adjacent polytopes of its $P P$ pair:

Fig. 2: Paired correspondences of $P P$ s for Class II (left \& middle), \& generically (all classes; right).

## 2. THE ASSOCIATED EVOLUTION OF NON-SEPARATING MORPHING FACES: CLASS II

As partially explored in earlier papers $[3,4]$ and further to the description in the previous section, as one set of faces separates, the other 2 sets of faces evolve. Refer Fig. 3 \& Table III.

In Class II, the neutral polytopes $\alpha \& \beta$ of level $1(L 1)$ are the edges of the $+\mathrm{ve} O H \&-\mathrm{ve} C B$, and the corresponding edges of the $+\mathrm{ve} T O \& T C$, respectively. $\alpha \& \beta$ complement one another:

Fig. 3: Rhombic schema of the levels of development of the polar facial polytopes:
(a)-(c) Class II -ve, ntrl, \& +ve facial polytopes; (d) Generic schema of all Classes I-V.

Negative Separations: On the Y-axis of the cubic schema going leftwards, as the -ve faces (cyan) separate, the +ve faces expand, evolving according to the rhombic schema of Fig. 3c from one level to the next higher level. Simultaneously, the neutral faces project (extrude), evolving to an analogous rhombic schema from one level to the next higher level (Fig. 3b). In Class II, as (lower rhomb) $V^{-}$s \& $S Q^{-} \mathrm{s}$ separate, $V^{+} \mathrm{s}$ expand to $T R^{+} \mathrm{s}$; while (upper rhomb) as $R S^{-} \mathrm{s}$ and $O G^{-} \mathrm{s}$ separate, $R T^{+} \mathrm{s}$ expand to $H X^{+} \mathrm{s}$; and meanwhile, (lower \& upper rhombs) $V^{0} \mathrm{~s}$ and $E_{\beta} \mathrm{s}$ project to $E_{\alpha} \mathrm{s}$ and $S Q^{0} \mathrm{~s}$, respectively (Fig. 1, lower left).

Neutral Separations: On the Z-axis of the cubic schema going upwards, as the neutral faces separate, both the +ve and the -ve faces expand, evolving according to the rhombic schema from one level to the next higher level (Fig. 3d). In Class II, as (front right rhomb) $V^{0} \mathrm{~s}$ and $E_{\beta}^{0} \mathrm{~s}$ separate, $V^{+} \mathrm{s}$ morph to $R T^{+} \mathrm{s}$; and as (back left rhomb) $E_{\alpha}^{0} \mathrm{~S}$ and $S Q^{0} \mathrm{~S}$ separate, $T R^{+} \mathrm{s}$ morph to $H X^{+} \mathrm{s}$. As (front left rhomb) $V^{0} \mathrm{~S} \& E_{\alpha}^{0} \mathrm{~S}$ separate, $V^{-} \mathrm{s}$ morph to $R S^{-} \mathrm{s}$; and as (back right rhomb) $E_{\beta}^{0} \mathrm{~s} \& S Q^{0} \mathrm{~s}$ separate, $S Q^{-} \mathrm{s}$ morph to $O G^{-} \mathrm{s}$ (Fig. 1, upper middle).

Positive Separations: On the X -axis of the schema going rightwards, as the +ve faces separate, the -ve faces expand, evolving according to the rhombic schema from one level to the next higher level (Fig. 3a). Meanwhile, the neutral faces project (extrude), evolving according to the analogous rhombic schema from one level to the next higher level (Fig. 3b). In Class II, as (lower rhomb) $V^{+} \mathrm{s} \& T R^{+} \mathrm{s}$ separate, $V^{-} \mathrm{s}$ expand to $S Q^{-} \mathrm{s}$; while (upper rhomb) as $R T^{+} \mathrm{s}$ and $H X^{+} \mathrm{s}$ separate, $R S^{-} \mathrm{s}$ expand to $O G^{-} \mathrm{s}$; meanwhile, (lower \& upper rhombs) $V^{0} \mathrm{~S}$ and $E_{\alpha}^{0} \mathrm{~s}$ extrude to $E_{\beta}^{0} \mathrm{~S}$ and $S Q^{0} \mathrm{~s}$, respectively (Fig. 1, lower right).

Fig. 4: On-axis Class II null, regular/quasi-regular (dashed), \& double (frequency) ( $0, \alpha \& \beta, 2$ ) faces from center $V T$ (circle) outwards and front to back for (left to right): +ve, ntrl, and -ve axes; null (0) refers to the 0D case; regular ( $\alpha$ ) to the same orientation face as for the regular $P L s(O H, C B)$, and quasiregular $(\beta)$ as for the quasi-regular $Q R(C O)$; and double (2) to the 2 -frequency face. Neutral $\alpha \& \beta$ faces are defined as the 2 -gon $E^{0}$ s of the + ve $\&-\mathrm{ve} P L s O H \& C B$, respectively.

The neutral faces (2-gon neutral edges of the $P P$ ) that are generated at the middle Level $1 L 1$ ) of the facial rhombic schema shown in Fig. 3 are of two kinds of orientations, $\alpha \& \beta$, depending on whether they characterize the +ve or $-\mathrm{ve} P L \mathrm{~s}$ (in Class II, $O H \& C B$ ), respectively. This is similar to the central $L 1$ distinction of the + ve and -ve faces into $\alpha \mid \beta$ orientations (Figs. 3b \& 4). The morphology of the $\alpha \mid \beta$ neutral dichotomy is analogous to that of the two kinds of neutral polyhedra of the Class III honeycombs, especially in the primary and tertiary arrays [5-11], where the neutral diverges into complementary pairs.

Table II. Generic Schema of the 5 Classes of the Regular \& Semi-regular Polyhedra \& Tilings.

| Polytope <br> Class | Symmetry <br> $\{0,+,-\}$ |  | Lower Rhomb |  |  |  | Upper Rhomb |  |  |  |  |

## 3. PAIRING OF POLYGONAL ARRAYS BY THE SEPARATION OF FACES: CLASS IV

Class IV of the regular and semiregular polytopes comprises the Tri-Hex arrays, where the polar polytopes are the + ve triangular and -ve hexagonal regular tessellations. A similar characterization to that made for Class II applies to Class IV, notwithstanding that it significantly differs, being of 2D tessellations, rather than 3D polyhedra, and unlike the other 2D Class V of the $S Q-S Q$ cluster of arrays, has polar elements of different geometric form.

Negative Separations: On the Y-axis of the cubic schema going leftwards, as (lower rhomb) $\mathrm{V}^{-} \mathrm{s} \& \mathrm{HX}^{-} \mathrm{s}$ separate, $V^{+}$s expand to $T R^{+} \mathrm{s}$; while (upper rhomb) as $R H^{-}$s and $D D^{-}$s separate, $R T^{+}$s expand to $H X^{+}$; and meanwhile, (lower \& upper rhombs) $V^{0} \mathrm{~s}$ and $E_{\beta} \mathrm{s}$ project to $E_{\alpha} \mathrm{S}$ and $S Q^{0} \mathrm{~s}$, respectively (Fig. 5, left).

Neutral Separations: On the Z-axis of the cubic schema going upwards, as (front right rhomb) $V^{0} \mathrm{~s}$ and $E_{\beta}^{0} \mathrm{~s}$ separate, $V^{+} \mathrm{s}$ morph to $R T^{+} \mathrm{s}$; as (back left rhomb) $E_{\alpha}^{0} \mathrm{~s}$ and $S Q^{0} \mathrm{~s}$ separate, $T R^{+} \mathrm{s}$ morph to $H X^{+} \mathrm{s}$. As (front left rhomb) $V^{0} \mathrm{~s} \& E_{\alpha}^{0} \mathrm{~s}$ separate, $V^{-} \mathrm{s}$ morph to $R H^{-} \mathrm{s}$; and as (upper right rhomb) $E_{\beta}^{0} \mathrm{~s} \& S Q^{0} \mathrm{~s}$ separate, $H X^{-}$s morph to $D D^{-}$s (Fig. 5, top).

Positive Separations: On the X -axis of the cubic schema going rightwards, as (lower rhomb) $V^{+} \mathrm{s}$ \& $T R^{+} \mathrm{s}$ separate, $V^{-} \mathrm{s}$ expand to $H X^{-} \mathrm{s}$; while (upper rhomb) as $R T^{+} \mathrm{s}$ and $H X^{+} \mathrm{s}$ separate, $R H^{-} \mathrm{s}$ expand to $D D^{-} \mathrm{s}$; meanwhile, (lower \& upper rhombs) $V^{0} \mathrm{~s}$ and $E_{\alpha}^{0} \mathrm{~s}$ extrude to $E_{\beta} \mathrm{s}$ and $S Q^{0} \mathrm{~s}$, respectively (Fig. 5, right).

Figure 5 on this page and the next show for each cluster:

## UPPER RHOMBUS:

Great Rhombic Tri-Hex Array (top);
Truncated Triangular Array | Truncated Hexagonal Array (upper left | right);
Quasi-Regular TriHex array (lower).
LOWER RHOMBUS:
Small Rhombic Tri-Hex array (upper);
Triangular Array | Hexagonal Array (lower left | right);
Verticial Array (bottom).

In this class, the hexagonal and triangular arrays are
 considered the -ve \& +ve polar polytopes, respectively, their facial axes being the -ve (light grey) and +ve (dark grey) axes.

Fig. 5: 2.5D Schema of faces: Pairing of the Class IV polyhedra according to their -ve (lower left), ntrl (upper left), and +ve (lower right), faces; with (previous page) their combined positive, neutral, and negative faces.

## 4. THE UNFOLDING OF APPARENT THREE-FOLD SYMMETRY

I had previously [3] exploited the 2D characteristics of the 2.5 D schema, integrating the vertical dimension, and associated separation of $P P$ elements into + ve (left; $\mathrm{OH}-\mathrm{TO}$ ), neutral (middle; $V P-C O-S R C O-G R C O$ ), and -ve (right; $C B-T C$ ). The 3D characteristics of the schema were partially employed, with primary differentiation into lower $(V P, O H, C B, S R C O$ ) and upper ( $C O, T O, T C, G R C O$ ) rhombi (top \& bottom faces of the cubic schema). Generically, this represents separation into positive $T P^{+}-P L^{+}$, neutral $V P-Q R-S R-G R$, and negative $P L^{--} T P^{-}$, with lower $\left(V P, P L^{+}, P L^{-}, S R\right.$ ) and upper $\left(Q R, T P^{+}, T P^{-}, G R\right)$ rhombi.

In this paper, these 3D characteristics are more fully developed by regarding the $\sqrt{3}$ long diagonal $V P$ GRCO as the primary axis, and situated vertically, so the cubic schema can be regarded as a cube balanced on one vertex ( $V P$ ) (Fig. 6b), hence demonstrating 3-fold symmetry: instead of considering +ve and -ve as polar opposites with neutral as central mediating case, the three gender cases of +ve , neutral, and -ve are allowed a measure of equal status, the main distinction being that the neutral faces (2-gon neutral edges of the $P P$ ) that are generated at Level 1 of the facial hierarchy are of two orientations, $\alpha \& \beta$, as before.

Considering the cubic schema in a true 3D multi-axial sense (in microgravity), it is evident that any $P P$ enjoys various kinds of pairing relationship with 3 adjoining $P P \mathrm{~s}, 3$ distant $P P \mathrm{~s}$, and 1 opposite $P P$; e.g. in Class II, $O H-T C: O H ; S R, V P, T O ; C O, G R, C B ; T C$. On the primary $V P-G R C O \sqrt{ } 3$ axis, the $V P$ shows a stepped progression through 3 neighboring $P P \mathrm{~s}, O H, C O, C B ; 3$ more distant relatives, $T C$, SRCO, TO; to culminate in its opposite, GRCO.

Fig. 6: (left) Class II rhombic bi-hierarchical network of $P P \mathrm{~s}$ (view +ve axis);
(right) Class II $V P — G R C O \sqrt{3}$ axis with stepped progression of $P P$ pairs of $V P$ to 1: $\mathrm{OH} / \mathrm{CO} / \mathrm{CB}$; to 2: TC/SRCO/TO; to 3. GRCO.

Therefore, regarding the $G R C O-V P$ diagonal as a unique vertical primary axis to the schema (restoring gravity), each of the $P P \mathrm{~s}$ can be regarded as a locus of realization and/or of generation of its neighboring $P P \mathrm{~s}$, and the $8 P P \mathrm{~s}$ of each class can then be ranked according to their pattern of relationship to their adjoining $P P$ s: $V P$ is unique, and in step 1 , generates 3 equivalent $P P$ s: $V P \rightarrow O H, C O, \& C B$. In step 2, $O H, C O, \& C B$ each generate two $P P$ s, i.e., $O H \rightarrow S R C O \& T O ; C O \rightarrow T O \& T C$; and $C B \rightarrow T C \&$ $S R C O$. In step 3, the equivalent $T C, S R C O$, \& $T O$ each generate the unique $G R C O: T C, S R C O, \& T O \rightarrow$ GRCO, to culminate the vertical progression. The constant feature of each step instance is the separation of faces of one gender $(-, 0,+)$ by unit distance, to indicate that this may be the driving characteristic.

Hence the schema displays clear stratification (as for the cubic polar zonahedron [12]), with each $P P$ being generated from, and/or developing into, its fellow $P P \mathrm{~s}$ (where $V T$ only generates; GRCO is only generated), there being 4 strata $(S)$ of elements: $S 1: V P ; S 2: O H, C O, \& C B ; S 3: T C, S R C O, \& T O$; and

S4: GRCO. The schema's morphology exhibits clear 3-fold order around the $V P-G R C O \sqrt{ } 3$ axis; each of the 5 Classes I-V of regular \& semi-regular polytopes according to symmetry is characterized by a development sheath of sequences from $V P$ to $G R$ of 3-fold nature, with the $P P$ s of a class disposed at those 4 strata.

Then for each of the five classes, each constituent $P P$ within that class can be developed by the separation of -ve , neutral, or +ve faces from the source $V P$ in a sequence of steps, so: 0 step: $V P ; 1$ step: $P L^{+}, Q R$, $P L^{-} ; 2$ steps: $T P^{-}, S R Q R, T P^{+} ; 3$ steps: $G R Q R$ (Fig. 7b). The variations in steps to realize a $P P$ by the separation of adjoining surface polytopes separating by unit distance to adjacent surface polytopes can be given as: no way: $V P$; one way: $P L^{+}, Q R, P L^{-}$; two ways: $T P^{-}, S R Q R, T P^{+}$; and six ways: $G R Q R$.

Fig. 7: The 3-fold order and pairing of polytopes by neutral faces and their separation:
(a) Class II, (b) Generic, i.e., for all 5 classes of symmetry, (c) Class IV.

For Class II, this is 0 step (variations in steps of no way), $\mathrm{VP}_{\mathrm{II}} ; 1$ step (1 way), $O H, C O, C B ; 2$ steps ( 2 ways), TC, SRCO, TO; 3 steps ( 6 ways), GRCO (Fig. 7a). For Class IV, this is 0 steps (no way), $V P_{\mathrm{IV}} ; 1$ step (1 way), TR, QR TR: $H X, H X ; 2$ steps (2 ways), $\operatorname{TrncHX}$, SR TR: HX, TrncTR; 3 steps (6 ways), GR TR: HX (Fig. 7c). (NB. Or, subduction sequences of facial convergence could consider GRQR $\rightarrow$ $\left.\left(T P^{+}, S R Q R, T P^{-}\right) \rightarrow\left(P L^{+}, Q R, P L^{-}\right) \rightarrow V P\right)$. Therefore, each family of polytopes demonstrates a high degree of order, and should not be thought of as being in any sense accidentally related; or within any one class, by assuming one $P P$ is equivalent to the other seven. Rather, they simultaneously crystallize into formal existence as regularly varied concretizations of an integral, profound natural spatial order.

The 3-fold morphology of the $8 P P \mathrm{~s}$ in each class shows the structure of a polar zonahedron, as also observed in the evolution/involution of the 2D polar zonagon. This geometry at higher frequency ( $f=$ ( $12,24,48,60 \ldots$ ) is used in Islamic sacred architecture of the dome, in the 3D form and in 2D surface decoration, as explored in part of my PhD [12:pp.9-34], and offers facile advantages to construction and decoration (equal subdivision of angle in plan; equal length edges; constant vertical gain of edges; corresponding equal vertical stratification of nodes; nodes lying on rotated sine wave surface). In sacred and traditional architecture, the form can eloquently symbolize the geometry of the center, projected into time and space; the cycle of manifestation and transformation of a central epiphany emanating from the source, extending to maximum realization in the phenomenal; then reflecting, clarifying, and centering, for the manifestation to be reabsorbed through the center, to return to the noumenal beyond creation.

But the 3 -fold symmetry of -ve, ntrl, and +ve is imperfect; consideration of the duality of the polyhedra indicates that the function of the neutral is different from that of the polar; there is a creative tension between this characterization and the unfolding of order from wrapping around a central axis, to reflective symmetry about a central vertical axis of neutrality; the sheath of the schema splits open to uncurl to dispose elements and relationships into bilateral symmetry of vertical qualitative differentiation, and horizontal duality/polarity. Hence the subtlety of the 2.5 D schema that can mediate that creative tension.

Table IV. Generic separation of one set of ( -ve , neutral, or +ve ) facial pairs of $P P$ s together with associated morphological changes of the other 2 sets of facial polytopes ( $F \mathrm{~s}$ ) from source to goal.

| Separating facial PTs | Primary Polytope $(P P)$ transition | Source Sals | Goal facial $P T \mathrm{~s}$ | Source Sacial $P T \mathrm{~s}$ | Goal facial $P T$ s |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Negative facial PT separation |  | Neutral facial PT projection |  | Positive facial PT expansion |  |
| $F_{0}^{-}$ | $V P \rightarrow P L^{+}$ | ${ }_{0} V_{0}^{0}$ | ${ }_{0} E_{\alpha}^{0}$ | ${ }_{0} V_{0}^{+}$ | ${ }_{0} F_{\alpha}^{+}$ |
| $F_{\alpha}^{-}$ | $P L^{-} \rightarrow S R Q R$ | ${ }_{0} E_{\beta}^{0}$ | ${ }_{0} F_{2}^{0}$ | ${ }_{1} V_{0}^{+}$ | ${ }_{1} F_{\alpha}^{+}$ |
| $F_{\beta}^{-}$ | $Q R \rightarrow T P^{+}$ | ${ }_{1} V_{0}^{0}$ | ${ }_{1} E_{\alpha}^{0}$ | ${ }_{0} F_{\beta}^{+}$ | ${ }_{0} F_{2}^{+}$ |
| $F_{2}^{-}$ | $T P^{-} \rightarrow$ GRQR | ${ }_{1} E_{\beta}^{0}$ | ${ }_{1} F_{2}^{0}$ | ${ }_{1} F_{\beta}^{+}$ | ${ }_{1} F_{2}^{+}$ |
| Neutral facial $P T$ separation |  | Positive facial PT expansion |  | Negative facial $P T$ expansion |  |
| $F_{0}^{0}$ | $V P \rightarrow Q R$ | ${ }_{0} V_{0}^{+}$ | ${ }_{0} F_{\beta}^{+}$ | ${ }_{0} V_{0}^{-}$ | ${ }_{0} F_{\beta}^{-}$ |
| $F_{\alpha}^{0}$ | $P L^{+} \rightarrow T P^{+}$ | ${ }_{0} F_{\alpha}^{+}$ | ${ }_{0} F_{2}^{+}$ | ${ }_{1} V_{0}^{-}$ | ${ }_{1} F_{\beta}^{-}$ |
| $F_{\beta}^{0}$ | $P L^{-} \rightarrow T P^{-}$ | ${ }_{1} V_{0}^{+}$ | ${ }_{1} F_{\beta}^{+}$ | ${ }_{0} F_{\alpha}^{-}$ | ${ }_{0} F_{2}^{-}$ |
| $F_{2}^{0}$ | $S R Q R \rightarrow G R Q R$ | ${ }_{1} F_{\alpha}^{+}$ | ${ }_{1} F_{2}^{+}$ | ${ }_{1} F_{\alpha}^{-}$ | ${ }_{1} F_{2}^{-}$ |
| Positive facial $P T$ separation |  | Negative facial PT expansion |  | Neutral facial PT projection |  |
| $F_{0}^{+}$ | $V P \rightarrow P L^{-}$ | ${ }_{0} V_{0}^{-}$ | ${ }_{0} F_{\alpha}^{-}$ | ${ }_{0} V_{0}^{0}$ | ${ }_{0} E_{\beta}^{0}$ |
| $F_{\alpha}^{+}$ | $\mathrm{PL}^{+} \rightarrow$ SRQR | ${ }_{1} V_{0}^{-}$ | ${ }_{1} F_{\alpha}^{-}$ | ${ }_{0} E_{\alpha}^{0}$ | ${ }_{0} F_{2}^{0}$ |
| $F_{\beta}^{+}$ | $Q R \rightarrow T P^{-}$ | ${ }_{0} F_{\beta}^{-}$ | ${ }_{0} F_{2}^{-}$ | ${ }_{1} V_{0}^{0}$ | ${ }_{1} E_{\beta}^{0}$ |
| $F_{2}^{+}$ | $T P^{+} \rightarrow G R Q R$ | ${ }_{1} F_{\beta}^{-}$ | ${ }_{1} F_{2}^{-}$ | ${ }_{1} E_{\alpha}^{0}$ | ${ }_{1} F_{2}^{0}$ |

These correspondences between classes of the various facial transformations of separation, morphing/expansion of the -ve or +ve faces or extrusion/projection of the neutral faces help validate the 2.5D schema and the rhombic schema of evolution of faces, while serving to characterize the progressions and interrelationships of the polyhedra and tessellations.

In the following Figs. 8 and 9, $\mathrm{F}=$ Face, including where relevant (on axis) null or degenerate $0 \mathrm{D} V T$ and $1 \mathrm{D} E$, as well as 2D polygons.

Right superscript: Polarity, of - , negative; 0 , neutral; or + , positive.
Left subscript: Spacing of faces of $\mathrm{d}=0$ : adjoining, or $\mathrm{d}=1$ : adjacent, with $1=$ edge length of polytope.
Right subscript: Hierarchical level of face: $0=V T$; $\alpha$ : single freq. +ve face of $+\mathrm{ve} P L P T$, or neutral face (edge) of polar +ve PT; $\beta$ : -ve (single freq.) face ("rotated") of $Q R P T$, or ntrl face ( $E$ ) of -ve PL PT ( $\alpha$ $\& \beta=$ level 1); 2: double freq. $-\mid+\mathrm{ve}$ face of $T P$ or $G R P T$ or ntrl face $/ S Q$ of $S R$ or $G R P T$.

Letting faces be null on-axis 0 D vertices or 1 D edges enables formal consistency across the $P P \mathrm{~s}$.
Taken together, $-\mathrm{ve}, \mathrm{ntrl}, \&+\mathrm{ve}$ faces form each polyhedron or tiling of the 5 symmetry classes.

Fig. 8: Generic 2.5D Schema of faces across classes, with exemplar Class II faces: Upper: ntrl faces. Left: -ve faces. Right: +ve faces. Lower: ntrl, -ve, \& +ve faces.

Fig. 9: Rotated Class II 2.5D Schema of faces: top/center: ntrl ( 0 rotation of schema); left: -ve faces ( $-2 \pi / 3$ rotation); right: +ve faces ( $+2 \pi / 3$ ). The $-\mathrm{ve} / \mathrm{ntrl} /+\mathrm{ve}$ faces combine to form each PT.

Faces are null; regular or quasi-regular (of the regular or quasi-regular $P$ ); or double ( $0, \alpha$ or $\beta$, or 2 ):

Fig. 10: Formal patterns for left to right -ve , ntrl, \& +ve clusters of faces of the cubic schema. Patterns of separation and morphing/extrusion are identical across faces, - ve \& +ve reflective.

## 5. INTEGRATING THE RELATIONSHIPS

The formal structure of elements of the five classes of regular and semiregular polyhedra and tessellations, and the relationships between the elements in any one class, become evident. The key is the 2.5D cubic schema in concert with the rhombic schema of the development of faces, reorienting the cube on its $\sqrt{ } 3$ long axis of $V P-G R$, and recognizing the separation of faces characterizing any one of the cubic schema links between polytopes as bundles/sheaths of parallel faces of the cube as zonahedron. Then either of the other 2 sets of characteristics of the simultaneous morphing or expansion of +ve or -ve facial polytopes, and the projection or extrusion of neutral facial polytopes, can be recognized as the other 2 zonahedral bundles of the zonahedral cube, respectively, though these are not simply equivalent to the neutral case that exploits the primary orthogonal axes of the rhomb, but are differentiated into pairs of pairs that exploit the inclined axes/opposite edges of the rhomb, separating $\mathrm{d}=0$ and 1 rhombs.

In the negative facial case (Fig. 10A), -ve front right cubic schema faces are adjoining $\mathrm{d}=0$, while back left are adjacent $\mathrm{d}=1$. On the Z-axis, the pairs of pairs are $2 \times(0 \rightarrow \beta) \& 2 \times(\alpha \rightarrow 2)$, where $\mathrm{d}=0:\left(0_{0} \rightarrow \beta_{0}\right)$ \& $\left(\alpha_{0} \rightarrow 2_{0}\right)$, and $\mathrm{d}=1:\left(0_{1} \rightarrow \beta_{1}\right) \&\left(\alpha_{1} \rightarrow 2_{1}\right)$. On the X-axis, the pairs of pairs are $2 \times(0 \rightarrow \alpha) \& 2 \times(\beta \rightarrow 2)$, where $\mathrm{d}=0:\left(0_{0} \rightarrow \alpha_{0}\right) \&\left(\beta_{0} \rightarrow 2_{0}\right), \mathrm{d}=1:\left(0_{1} \rightarrow \alpha_{1}\right) \&\left(\beta_{1} \rightarrow 2_{1}\right)$.

In the neutral facial case (Fig. 10B), neutral lower cubic schema faces are adjoining $\mathrm{d}=0$, while upper are adjacent $\mathrm{d}=1$. On the X -axis, the pairs of pairs are $2 \times(0 \rightarrow \beta) \& 2 \times(\alpha \rightarrow 2)$, where $\mathrm{d}=0:\left(0_{0} \rightarrow \beta_{0}\right)$ \& $\left(\alpha_{0} \rightarrow 2_{0}\right)$, and d=1: $\left(0_{1} \rightarrow \beta_{1}\right) \&\left(\alpha_{1} \rightarrow 2_{1}\right)$. On the Y-axis, the pairs of pairs are $2 \times(0 \rightarrow \alpha) \& 2 \times(\beta \rightarrow 2)$, where $\mathrm{d}=0:\left(0_{0} \rightarrow \alpha_{0}\right) \&\left(\beta_{0} \rightarrow 2_{0}\right), \mathrm{d}=1:\left(0_{1} \rightarrow \alpha_{1}\right) \&\left(\beta_{1} \rightarrow 2_{1}\right)$.

In the positive facial case (Fig. 10C), + ve front left cubic schema faces are adjoining $\mathrm{d}=0$, while back right are adjacent $\mathrm{d}=1$. On the Y-axis, the pairs of pairs are $2 \times(0 \rightarrow \alpha) \& 2 \times(\beta \rightarrow 2)$, where $\mathrm{d}=0:\left(0_{0} \rightarrow \alpha_{0}\right)$ $\&\left(\beta_{0} \rightarrow 2_{0}\right)$, and $\mathrm{d}=1$ : $\left(0_{1} \rightarrow \alpha_{1}\right) \&\left(\beta_{1} \rightarrow 2_{1}\right)$. On the Z -axis, the pairs of pairs are $2 \times(0 \rightarrow \beta) \& 2 \times(\alpha \rightarrow 2)$, where d=0: $\left(0_{0} \rightarrow \beta_{0}\right) \&\left(\alpha_{0} \rightarrow 2\right), \mathrm{d}=1:\left(0_{1} \rightarrow \beta_{1}\right) \&\left(\alpha_{1} \rightarrow 2_{1}\right)$.

In each case of $-\mathrm{ve}, \mathrm{ntrl}, \&+\mathrm{ve}$ clusters of faces, the separation of faces by gender is represented as the Y-, Z-, or X-axis separating rhombic schema of $0 \rightarrow \alpha \mid \beta \rightarrow 2$ for $d=0 \rightarrow d=1$.

Generically, for any one class, and for each case of -ve, neutral, or +ve facial polytope, each constituent $P P$ can be uniquely described in terms of two parameters: 1 . The level of facial polytope evolution, i.e., $(0, \alpha, \beta, 2)$, and 2. the separation of facial polytope distance, whether adjoining or adjacent, i.e., $(0,1)$. The $P P$ s are tabulated by $F$ evolution \& separation:

Table V. Constituent PPs of each class as generic expressions of facial evolution and separation.

| Separation | Negative |  |  |  |  | Poutral |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| d | 0 | $\alpha$ | $\beta$ | 2 | 0 | $\alpha$ | $\beta$ | 2 | 0 | $\alpha$ | $\beta$ | 2 |  |  |
| 0 | $V P$ | $P L^{-}$ | $Q R$ | $T P^{-}$ | $V P$ | $P L^{+}$ | $P L^{-}$ | $S R$ | $V P$ | $P L^{+}$ | $Q R$ | $T P^{+}$ |  |  |
| 1 | $P L^{+}$ | $S R$ | $T P^{+}$ | $G R$ | $Q R$ | $T P^{+}$ | $T P^{-}$ | $G R$ | $P L^{-}$ | $S R$ | $T P^{-}$ | $G R$ |  |  |

Any one case: -ve, neutral, or +ve of the facial polytope, in combination with the separation (Sep.) of those neighboring facial polytopes of adjoining ( $\mathrm{d}=0$ ) or adjacent $(\mathrm{d}=1)$, is sufficient information to determine the $P P$ of that class, whether $V P, P L^{-/+}, Q R / S R, T P^{-/+}$, or $G R$. Excepting the $Q R / S R$ pair, the -ve and +ve cases are reflectively symmetric about the $V P-G R$ axis, while the neutral case shows different structure, which suggests that my neutral annotation and analysis might be improved. The overall structure indicates that as well as the obvious $P L^{-/+}$and $T P^{-/+}$polarities, there is limited $Q R / S R$ polarity.

Generically, for any one class, and for each case of -ve, neutral, or +ve facial polytope, each constituent $P P$ can alternatively be uniquely described according to its property of gendered -ve , neutral, and/or +ve facial separation, hence $\mathrm{d}_{-0+}=0$ or 1 :

Table VI. Constituent PPs of each class as generic expressions of facial separation $\mathrm{d}=|-0+|$.

|  |  |  |

This returns the tentative 3-fold order to bilateral symmetry, and the historical perspective of the perfection of the regular PLs, though elsewhere I make an alternative case that it is the $Q R \mathrm{~s}$ that are perfect, while the $P L s$ are extremes [13]. But given that these polyhedra and tessellations are discovered as projections of the noumenal (ideal) into the phenomenal (contingent) realm, the enigmatic possibility remains that such limited 3-fold symmetry represents a trace of primordial evolution of formal symmetry, suggests that the constraints and properties of space that we encounter might at the cosmic level be subject to change, and raises the intriguing question of whether such change would be abrupt or gradual. One might speculate whether in our cosmos, three-fold symmetry is unstable (e.g., is it common in the animal kingdom? It seems at least uncommon); and to be subsumed into a kind of 2-step bilateral symmetry that I intend to address in a subsequent paper, which is characterized by complementary forms as (-ve $\leftrightarrow$ +ve ), rather than identical, allowing the tentative self-reflective quality of the neutral ( $V P \leftrightarrow G R$ and $Q R$ $\leftrightarrow S R)$ ). Further, can these patterns and their harmonic order be correlated with quantum forms and field behavior, where resonance seems a fundamental quality?

Fig. 11: Expansion of 2.5 D cubic schema to demonstrate the rhombic schema on each of its six faces. Lower left, bottom, \& lower right outermost faces show +ve, ntrl, and $-\mathrm{ve}(\mathrm{d}=0)$ adjoining rhombic schema; upper right, top, and upper left outermost faces show +ve , ntrl, and $-\mathrm{ve}(\mathrm{d}=1)$ adjacent rhombic schema.

Fig. 12: Bi-rhombic (cubic) schema for the -ve (left), ntrl (center), and + ve (right) faces, abstracted from the outer 6 faces of the extended 2.5D schema in the previous figure. For consistency, 3 views are taken through the cube, one per cluster, from (outside) adjacent ( $\mathrm{d}=1$ ) to (inside) adjoining ( $\mathrm{d}=0$ ) faces.

In each cluster of Fig. 12, lower rhomb is of adjoining faces ( $\mathrm{d}=0$ ) of the polytope, upper rhomb is of the corresponding adjacent faces $(\mathrm{d}=1)$. Vertical links indicate these corresponding pairs. Each rotated rhomb traces the same progression of $<0 \rightarrow \alpha \mid \beta \rightarrow 2>$ of lower level 0-polytope, level $1 \alpha \& \beta$ polyhedra, and level 2 polyhedra. The -ve and ntrl clusters show $\alpha$ at left, while +ve shows $\beta$ at left. Note the subtle "circulation" of polyhedra at the mid-levels from cluster to cluster; only the ntrl shows the initial schema, while the $+\mathrm{ve} \&-\mathrm{ve}$ are rotated. These clusters correspond to those of Fig. 8, so the -ve schema (cluster) is rotated counter-clockwise ( $-2 \pi / 3$ ) from the ntrl schema (cluster) about the vertical $G R-V P$ main $\sqrt{ } 3$ axis, while the + ve schema is rotated clockwise $(+2 \pi / 3)$; bear in mind that in this figure, the polyhedra of the schema rotate (as a group), while their relationships (the schema edges) are conserved through the three states of -ve , ntrl, and +ve .

Fig. 13: The simultaneous various facial evolutions. Double lines of cyan, yellow, magenta denote the separation of faces for the respective $-\mathrm{ve} \mathrm{Y}, \mathrm{ntrl} \mathrm{Z}$, +ve X (lower left, top, lower right) axes. Single lines of varied dash of such coloring denote the simultaneous evolution of faces of two paired $(0 \rightarrow \alpha) \&(\alpha \rightarrow 2)$, and $(0 \rightarrow \beta) \&(\beta \rightarrow 2)$, with $P P$ faces cyan, yellow, magenta, respectively. In each schematic cube, the 4 $-\mathrm{ve}, \mathrm{ntrl}$, or +ve parallel lines denoting the evolution of faces correspond to the bundles of edges of the three zones of the cubic zonahedron. The double line zonal bundle separates the two faces of the schematic cube as enantiomorph of the rhombic schema, the polytopes of one face for $\mathrm{d}=0$ where faces adjoin (sharing a common vertex or edge), while those of the opposing face for $\mathrm{d}=1$ where the faces are adjacent (separated by unit distance). The -ve , ntrl, +ve rhombs for the $\mathrm{Y}, \mathrm{Z}, \mathrm{X}$ axes are abstracted at top left, bottom, top right, respectively. All 3 cubic schema apply simultaneously; the -ve and +ve cubic schema are bilaterally symmetric, the transformations of the schema applying to the relationships (edges), not the $P P$ s. All five classes demonstrate the same morphology, allowing for the dimensional difference between the polyhedra and polygonal tessellations (Classes I-III $c f$. IV \& V).

## 6. CONCLUSION

Earlier apprehension $[11,12]$ suggested that the elegance of the regular and semiregular polyhedra and tessellations was surely matched by their order, and has inspired subsequent research.

Fig. 14: Separation of faces by $-\mathrm{ve} / \mathrm{ntrl} /+\mathrm{ve}$ gender. Each transition $P P_{0} \rightarrow P P_{1}$ is characterized by a separation of neighboring faces from adjoining $(\mathrm{d}=0$ ) to adjacent $(\mathrm{d}=1)$, in $3 \mathrm{X}, \mathrm{Y}, \mathrm{Z}$ zones. Left to right: Generic, Class II polytopes, \& IDs. $P P$ s evolve (devolve) upwards (downwards) $V P \rightarrow G R(G R \rightarrow V P)$.
Inspection of this schema (Fig. 14) shows that any $P P$ transition $P P_{0} \rightarrow P P_{1}$ is characterized by a separation of neighboring faces from adjoining $(\mathrm{d}=0)$ to adjacent $(\mathrm{d}=1)$, in one of the $3 \mathrm{X}, \mathrm{Y}$, or Z zones.

Fig. 15: Simultaneous transformation of faces by $(0 \rightarrow \alpha \mid \beta \rightarrow 2)$ evolution. As faces of one $-\mathrm{ve} / \mathrm{ntrl} /+\mathrm{ve}$ gender separate, faces of the remaining two genders transform, in pairs of transitions of $\boldsymbol{P} \boldsymbol{P}$ s of each zone. Quartiles show facial evolutionary stage, with zones in $(0 \rightarrow \alpha, \beta \rightarrow 2)$ or $(0 \rightarrow \beta, \alpha \rightarrow 2)$ pairs. Midpoints conserve facial separation, each zone with $1(0, \alpha, \beta, 2)$ face. Left to right: -ve; ntrl; +ve faces.

Figure 15 demonstrates that for each case of -ve , ntrl, and +ve faces, as one zone of the cubic schema represents the separation of -ve , ntrl, or +ve faces, respectively, one of the other two zones represents two pairs of parallel $0 \rightarrow \alpha$ and $\beta \rightarrow 2$ transitions, while the other zone represents two pairs of parallel $0 \rightarrow \beta$ and $\alpha \rightarrow 2$ transitions. Figure 16 shows that for each case of -ve , ntrl, and +ve faces, the $\mathrm{X}, \mathrm{Y}$, or Z axial zone of separation of faces representing $0 \rightarrow 0, \alpha \rightarrow \alpha, \beta \rightarrow \beta$, and $2 \rightarrow 2$ of the cubic schema of $\mathrm{d}=0$ and $\mathrm{d}=1$, respectively, separates two corresponding rhombic schema of $\mathrm{d}=0$ and $\mathrm{d}=1$, respectively, as previously shown in Fig. 10.

Fig. 16. $Y, Z, \& X$ zone separation of $d=0 \& d=1$ rhombic schema of $-v e, n t r l$, $+v e$ faces ( $L$ to $R$ ).
Thus, the separation of faces appears fundamental to the progression of $P P$ s represented by the edges of the cubic schema. That separation of faces for one gender is complemented by the simultaneous morphing of the faces of the other two genders according to either of two opposite edges of the rhombic schema of ( $0 \rightarrow \alpha$ and $\beta \rightarrow 2$ ), or ( $0 \rightarrow \beta$ and $\alpha \rightarrow 2$ ), respectively.

This elegant morphology appears to characterize the order of the regular and semi-regular polyhedra and tessellations. Consequent upon the assumption of a null polytope in each of the five symmetry classes; the assumption of degenerate 0 D and 1D facial polytopes of certain vertices and edges by gender; the cubic schema of $P P$ s; its rotation to the vertical $V P \rightarrow G R \sqrt{3}$ axis; the rhombic schema (in both enantiomorphs) of null 0 , regular $\alpha$ or quasi-regular $\beta$, and $2 f$ faces; the notion of limited 3 -fold symmetry to the order; the fundamental separation of faces $\mathrm{d}=0$ to $\mathrm{d}=1$; and accommodation of the transitional form of the snub enantiomorphs of each class at the center of the cubic schema, at the mid-point of the $S R Q R$ $Q R$ jitterbug and main $V P-G R$ axes, the order of the polyhedra and tessellations is herein adequately described.

This work might find application to diverse fields of polyhedral geometry, crystallography, chemistry (phase transitions, bi-polymers, smart polymers, catalysts), artificial bone matrix integrating variable flexibility, biomedicine (triggered deployment of dosage of drug from nanocages), smart material, wearable (conformable) electronics, space structures (dynamic structures, deployable antennae in Space), nanostructures, perhaps quantum mechanics and field theory, and potentially the nature of space itself. Future research is intended to refine the order of the all-space-filling periodic arrays of 2D \& 3D PTs in the light of this cubic schema.

Historically, the regular (and semi-regular) polyhedra as independent entities have been recognized as perfect (and semi-perfect) forms. However, while such formal perfection should at the very least be matched in their overall structure and morphology, I am unaware of any adequate order having previously been advanced. This paper redresses that shortfall with reference to the separation of one set of $+\mathrm{ve}, \mathrm{ntrl}$, or - ve faces characterizing the zonahedral progression of $P P_{1}$ to $P P_{2}$ on the rotated 2.5D cubic schema, while the other two sets of faces evolve according to the rhombic schema. It has been a privilege to glimpse such perfection.

Nomenclature: non-dimensional: -ve, negative; ntrl, neutral; +ve, positive; $f$, frequency (of $F$ ); $G R$, great rhombic; $L 0-L 2$, level $(0,1=\alpha \& \beta, 2)$ of rhombic schema; $P$, pole or polar; $S 1-4$, strata ( $1-4$ ) of rotated cubic schema; Snb, snub; $S R$, small rhombic; $\operatorname{Trnc}$, truncated. • zero-dimensional: $V^{0}$, neutral vertex ( $N V$ ); $V$, vertex (but can be 1 or 2 D ' $F$ '); $V P$, verticial polytope hence $V P_{I-V}$ • one-dimensional: $d$, distance of proximal $F \mathrm{~s}(0$ or 1$)$; $E$, edge ( $E G$ ) but here can be 2D ' $F$ '; $E^{0}$, neutral edge $(N E)$ but here 2D 2-gon ' $F$ '. - two-dimensional: $D D$, dodecagon (12-gon); $H X$, hexagon or hexagonal array; $O G$, octagon; $P R$, polar polygon; $R H$, rotated hexagon; $R P$, 'rotated' polar polygon (trunc.); $R S$, 'rotated' (trunc.) square; $R T$, 'rotated’ (trunc.) triangle; $R X$, 'rotated’ (trunc.) hexagon; $S Q$, square; $S Q^{0}$, neutral square ( $N S$ ); $S Q: S Q$, square-square array; $T P$, truncated polar polygon ( $2 f$ ); $T R$, triangle or triangular array; TR: $H X$, tri-hex array; $\operatorname{TrncHX}$, truncated hexagonal array; $\operatorname{TrncTR}$, truncated triagonal array; $Z G$, zonagon. - three-dimensional: $C B$, cube; $C O$, cuboctahedron; $D C$, dodecahedron; $G R C O$, great rhombic cuboctahedron; $I C$, icosahedron; $I C: D C$, icosidodecahedron; $O H$, octahedron; $O H: C B$, octahexahedron (=CO); SnbCO, snub cuboctahedron; $S R C O$, small rhombic cuboctahedron; TC, truncated cube; TD, truncated dodecahedron; $T H$, tetrahedron; $T H: T H$, tetra-tetrahedron (Class I colored $O H$ ); TI, truncated icosahedron; $T O$, truncated octahedron; $T P$, truncated polar polytope; $T T$, truncated tetrahedron; $Z H$, zonahedron. $\bullet$ multi-dimensional: $F$, face = facial $P T$ (in this paper, 0D, 1D, or 2D); $\alpha$, regular facial polytope; $\beta$, quasiregular facial polytope; $G R Q R$, great rhombic quasiregular; $P L$, polar polytope; $P P$, primary polytope; $P T$, polytope; $Q R$, quasiregular; $S n b Q R$, snub quasiregular; $S R Q R$, small rhombic quasiregular.

Robert C. Meurant $\square$ B.Arch (Hons) (1978), and PhD in Architecture (1984), University of Auckland, New Zealand $\square$ MA in Applied Linguistics (2007), University of New England, Australia $\square$ Director Emeritus, Institute of Traditional Studies, founded $1984 \square$ Taught in universities in New Zealand, the United States, and Korea $\square$ Published 6 books, 70 papers, presented papers in New Zealand, the U.S., the U.K., Japan, and Korea $\square$ For many years, a director of the Science \& Engineering Research Support Society (SERSC), Korea $\square$ Research interests: sacred and traditional geometry, art, and architecture; the traditional philosophy of art; number and form; the polyhedra; structural morphology and geometry; deployable Space habitation and large-scale structures in microgravity, nanoarchitecture, applied linguistics
